# Lecture 6

## Deque

### Linked List Based

# Course Roadmap

---

## Part 1: Linear Data Structures

Lecture 1: Complexity Analysis & Recursion

Lecture 2: Arrays

Lecture 3: Linked List

Lecture 4: Stack

Lecture 5: Queue

**Lecture 6: Deque**

Lecture 7: STL in C++ (Linear Data Structures)

# Lecture Agenda

We will discuss in this lecture  
the following topics

- 1- Introduction to Deque
  - 2- Insertion Operation
  - 3- Deletion Operation
  - 4- Front & Back Operations
  - 5- Traverse Operation
  - 6- Time Complexity & Space Complexity
-

Let's  
**STARTUP**

# Lecture Agenda

---

**Section 1: Introduction to Deque**

Section 2: Insertion Operation

Section 3: Deletion Operation

Section 4: Front & Back Operations

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

# Introduction to Deque

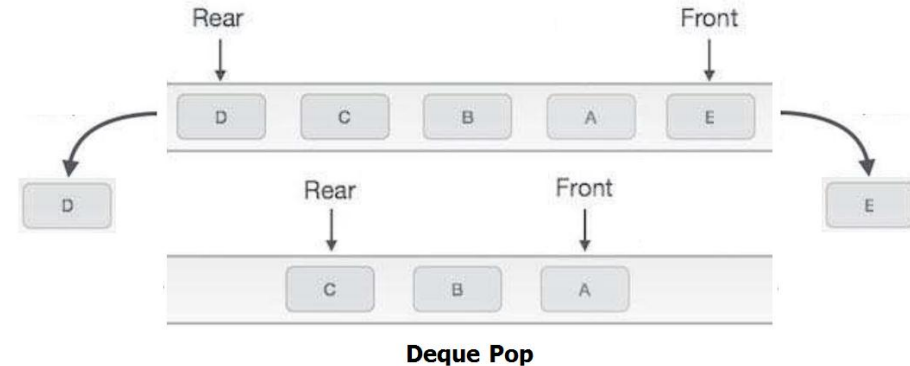

---

- **A double-ended queue (abbreviated to deque)** is an abstract data type that generalizes a queue, for which elements can be added to or removed from either the front (head) or back (tail). It is also often called a head-tail linked list.
- **A deque, also known as a double-ended queue**, is an ordered collection of items similar to the queue. It has two ends, a front and a rear, and the items remain positioned in the collection. What makes a deque different is the unrestrictive nature of adding and removing items. New items can be added at either the front or the rear. Likewise, existing items can be removed from either end. In a sense, this hybrid linear structure provides all the capabilities of stacks and queues in a single data structure.
- **A deque, also known as a double-ended queue** where by it has two ends, a front and a rear, and the items remain positioned in the collection. New items can be added or removed at either the front or the rear. It does not require the LIFO and FIFO orderings that are enforced by those data structures. It is up to you to make consistent use of the addition and removal operations.

# Introduction to Deque

- **Deque operations** may involve initializing or defining the deque, utilizing it, and then completely erasing it from the memory. Here we shall try to understand the basic operations associated with deques
- `insert begin()` - adds a new item to the front of the deque.
  - `insert end()` - adds a new item to the rear of the deque.
  - `delete begin()` - removes the front item from the deque.
  - `delete end()` - removes the rear item from the deque.

# Introduction to Deque

➤ **Following are the basic operations supported by a deque.**

- Insert (begin & end) - adds a new item to the front & rear of the deque.
- Delete (begin & end) - removes the front & rear item from the deque.
- Front & Back: which gets the first element and the last element in the queue.

➤ **Deque Types**

## 1. Deque (Linked List Based)

## 2. Deque (Array Based)

# Deque (Linked List Based) Node

## ➤ Initialize a global struct

```
#include <bits/stdc++.h>
using namespace std;

// A deque node
struct node {
    int data;
    node* prev;
    node* next;
};

// Initialize a global pointers for head and tail
node* head;
node* tail;
```

Deque-Linked-  
List-Based.cpp

# Lecture Agenda

✓ Section 1: Introduction to Deque

**Section 2: Insertion Operation**

Section 3: Deletion Operation

Section 4: Front & Back Operations

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

# Insertion Operation - Deque (Linked List Based)

- **Insert Operation** is to add (store) an item to the deque.
- Insert at begin 5

- **Insertion Algorithm:**

1. *create a new node*
2. *new node data = data*
3. *if head == NULL then head = new node*
4. *tail = new node*
5. *otherwise new node next = head*
6. *head prev = new node*
7. *head = new node*

# Insertion Operation - Deque (Linked List Based)

```
// This function inserts a node at the begin of the deque
void insert_begin(int new_data) {
    // allocate new node and put it's data
    node* new_node = new node();
    new_node->data = new_data;
    // check if the deque is empty
    if (head == NULL) {
        head = new_node;
        tail = new_node;
    }
    // otherwise insert the new node in the begin of the deque
    else {
        // set next of the new node to be the head and vice versa
        new_node->next = head;
        head->prev = new_node;
        // set the new node as a head
        head = new_node;
    }
}
```

Deque-Linked-  
List-Based.cpp

# Insertion Operation - Deque (Linked List Based)

- **Insert Operation** is to add (store) an item to the deque.

- Insert at end 1

- **Insertion Algorithm:**

1. *create a new node*
2. *new node data = data*
3. *if head == NULL then head = new node*
4. *tail = new node*
5. *otherwise new node prev = tail*
6. *tail next = new node*
7. *tail = new node*

# Insertion Operation - Deque (Linked List Based)

```
// This function inserts a node at the end of the deque
void insert_end(int new_data) {
    // allocate new node and put it's data
    node* new_node = new node();
    new_node->data = new_data;
    // check if the deque is empty
    if (head == NULL) {
        head = new_node;
        tail = new_node;
    }
    // otherwise reach the end of the deque
    else {
        // set the next of the last node to be the new node and vice versa
        tail->next = new_node;
        new_node->prev = tail;
        // set the new node as a tail
        tail = new_node;
    }
}
```

**Section 3: Deletion Operation**

Section 4: Front & Back Operations

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

# Deletion Operation - Deque (Linked List Based)

- **Delete Operation** remove (access) an item from the queue.

- **Deletion Algorithm:**

1. **temp node** = **head**
2. **if head equal tail** **then**
3.     **delete temp node**
4.     **head = tail = NULL**
5. **otherwise head = head next**
6.     **head prev = NULL**
7.     **delete temp node**

- Delete at begin 5

# Deletion Operation - Deque (Linked List Based)

```
// This function deletes the first node in the deque
void delete_begin() {
    // check if the deque is empty
    if (head == NULL)
        return;
    // get the node which it will be deleted
    node* temp_node = head;
    // check if the deque contain only one node
    if (head == tail) {
        delete(temp_node); // delete the temp node
        head = tail = NULL;
    }
    // otherwise the deque contain nodes more than one
    else {
        // shift the head to be the next node
        head = head->next;
        head->prev = NULL;
        delete(temp_node); // delete the temp node
    }
}
```

Deque-Linked-  
List-Based.cpp

# Deletion Operation - Deque (Linked List Based)

- **Delete Operation** remove (access) an item from the queue.

- **Deletion Algorithm:**

1. **temp node** = **tail**
2. **if head equal tail** **then**
3.     **delete temp node**
4.     **head = tail = NULL**
5. **otherwise** **tail = tail prev**
6.     **tail next = NULL**
7.     **delete temp node**

- Delete at end 1

# Deletion Operation - Deque (Linked List Based)

```
// This function deletes the last node in the deque
void delete_end() {
    // check if the deque is empty
    if (head == NULL)
        return;
    // get the node which it will be deleted
    node* temp_node = tail;
    // check if the deque contain only one node
    if (head == tail) {
        delete(temp_node); // delete the temp node
        head = tail = NULL;
    }
    // otherwise the deque contain nodes more than one
    else {
        // jump the deleted node
        tail = tail->prev;
        tail->next = NULL;
        delete(temp_node); // delete the node which selected
    }
}
```

Deque-Linked-  
List-Based.cpp

✓ Section 3: Deletion Operation

**Section 4: Front & Back Operations**

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

# Front & Back Operations - Deque (Linked List Based)

- **Front Operation** gets the first item in the deque.
- Front 5

- **Front Algorithm:**

1. *return head*

- **Back Operation** gets the last item in the deque.
- Back 1

- **Back Algorithm:**

1. *return tail*

# Front & Back Operations - Deque (Linked List Based)

```
// This function returns the value of the first element in the deque
int front() {
    // check if the deque is empty
    // to return the biggest integer value as an invalid value
    if (head == NULL)
        return INT_MAX;
    // otherwise return the real value
    else
        return head->data;
}

// This function returns the value of the last element in the deque
int back() {
    // check if the deque is empty
    // to return the biggest integer value as an invalid value
    if (tail == NULL)
        return INT_MAX;
    // otherwise return the real value
    else
        return tail->data;
}
```

Deque-Linked-

- ✓ Section 4: Front & Back Operations

**Section 5: Traverse Operation**

Section 6: Time Complexity & Space Complexity

# Traverse Operation - Deque (Linked List Based)

- **Traverse Operation** You start at the head of the list and continue until you come across a node that is.
- Traverse this deque

- **Traverse Algorithm:**
  1. *curr = head*
  2. *print curr data*
  3. *curr = curr next*
  4. *Repeat Step 2 if curr not equal NULL*

# Traverse Operation - Deque (Linked List Based)

```
// This function prints the contents of the deque
void print_deque() {
    // print the data nodes starting from head till reach the last node
    node* curr = head;
    while (curr != NULL) {
        cout << curr->data << ' ';
        curr = curr->next;
    }
}

// This function prints the contents of the deque
void print_deque_reverse() {
    // print the data nodes starting from tail till reach the first node
    node* curr = tail;
    while (curr != NULL) {
        cout << curr->data << ' ';
        curr = curr->prev;
    }
}
```

# Functionality Testing - Deque (Linked List Based)

## ➤ Initialize a global struct

```
#include <bits/stdc++.h>
using namespace std;

// A deque node
struct node {
    int data;
    node* prev;
    node* next;
};

// Initialize a global pointers for head and tail
node* head;
node* tail;
```

Deque-Linked-  
List-Based.cpp

# Functionality Testing - Deque (Linked List Based)

➤ In the Main function:

```
cout << "Deque front: " << front() << " and Deque back: " << back() << '\n';
cout << "Deque items forward: ";
print_deque();
cout << '\n';
cout << "Deque items backward: ";
print_deque_reverse();
cout << '\n';
cout << "adding the following elements 10 20 30 40 50\n";
insert_end(10);
insert_end(20);
insert_end(30);
insert_end(40);
insert_end(50);
cout << "the above elements have been added to the deque\n";
```

➤ Expected Output:

```
Deque front: 2147483647 and Deque back: 2147483647
Deque items forward:
Deque items backward:

adding the following elements 10 20 30 40 50
the above elements have been added to the deque
```

Practice

# Practice

---

- 1- Reverse string using stack
- 2- Check string is palindrome or not
- 3- Convert Infix Expression to Postfix Expression
- 4- Convert Infix Expression to Prefix Expression
- 5- Convert Postfix Expression to Infix Expression
- 6- Convert Prefix Expression to Infix Expression
- 7- Convert Postfix Expression to Prefix Expression
- 8- Convert Prefix Expression to Postfix Expression
- 9- Evaluation of Postfix Expression
- 10- Reverse a stack using recursion
- 11- Check for balanced parentheses in an expression
- 12- Length of the longest valid substring
- 13- Minimum number of bracket reversals needed to make an expression balanced
- 14- Next Greater Element
- 15- Delete middle element of a stack

# Practice

---

- 16- Reverse individual words
- 17- Largest Rectangular Area in a Histogram
- 18- Find maximum depth of nested parenthesis in a string
- 19- Expression contains redundant bracket or not
- 20- Check if two expressions with brackets are same
- 21- Delete consecutive same words in a sequence
- 22- Remove brackets from an algebraic string
- 23- Range Queries for Longest Correct Bracket Subsequence
- 24- Check if stack elements are pairwise consecutive
- 25- Reverse a number using stack
- 26- Tracking current Maximum Element in a Stack
- 27- Decode a string recursively encoded as count followed by substring
- 28- Find maximum difference between nearest left and right smaller elements
- 29- Find if an expression has duplicate parenthesis or not
- 30- Find index of closing bracket for a given opening bracket in an expression

# Practice

---

- 31- Sliding Window Maximum summation of all sub-arrays of size  $k$
- 32- Check string is palindrome or not
- 33- Generate Binary Numbers from 1 to  $n$
- 34- Reversing a queue using recursion
- 35- Reversing the first  $K$  elements of a Queue
- 36- Find the largest multiple of 3
- 37- Smallest multiple of a given number made of digits 0 and 9 only
- 38- Minimum time required to rot all oranges
- 39- Sum of minimum and maximum elements of all subarrays of size  $k$
- 40- First negative integer in every window of size  $k$

# Assignment

# Implement STL Deque

---

- Deque (usually pronounced like "deck") is an irregular acronym of double-ended queue. Double-ended queues are sequence containers with dynamic sizes that can be expanded or contracted on both ends (either its front or its back).
- Specific libraries may implement deques in different ways, generally as some form of dynamic array. But in any case, they allow for the individual elements to be accessed directly through random access iterators, with storage handled automatically by expanding and contracting the container as needed.
- Therefore, they provide a functionality similar to vectors, but with efficient insertion and deletion of elements also at the beginning of the sequence, and not only at its end. But, unlike vectors, deques are not guaranteed to store all its elements in contiguous storage locations: accessing elements in a deque by offsetting a pointer to another element causes undefined behavior.
- Double ended queues are sequence containers with the feature of expansion and contraction on both the ends. They are similar to vectors, but are more efficient in case of insertion and deletion of elements. Unlike vectors, contiguous storage allocation may not be guaranteed.

# Implement STL Deque

---

- Both vectors and deques provide a very similar interface and can be used for similar purposes, but internally both work in quite different ways: While vectors use a single array that needs to be occasionally reallocated for growth, the elements of a deque can be scattered in different chunks of storage, with the container keeping the necessary information internally to provide direct access to any of its elements in constant time and with a uniform sequential interface (through iterators). Therefore, deques are a little more complex internally than vectors, but this allows them to grow more efficiently under certain circumstances, especially with very long sequences, where reallocations become more expensive.
- Double Ended Queues are basically an implementation of the data structure double ended queue. A queue data structure allows insertion only at the end and deletion from the front. This is like a queue in real life, wherein people are removed from the front and added at the back. Double ended queues are a special case of queues where insertion and deletion operations are possible at both the ends. The functions for deque are same as vector, with an addition of push and pop operations for both front and back.

# Implement STL Deque

---

- Member functions:    **(constructor)** Construct vector (public member function)  
                              **(destructor)** Vector destructor (public member function)  
                              **(operator=)** Assign content (public member function)
- Iterators:            **(begin)** Return iterator to beginning (public member function)  
                              **(end)** Return iterator to end (public member function)  
                              **(rbegin)** Return reverse iterator to reverse beginning (public member function)  
                              **(rend)** Return reverse iterator to reverse end (public member function)  
                              **(cbegin)** Return const\_iterator to beginning (public member function)  
                              **(cend)** Return const\_iterator to end (public member function)  
                              **(crbegin)** Return const\_reverse\_iterator to reverse beginning (public member function)  
                              **(crend)** Return const\_reverse\_iterator to reverse end (public member function)

# Implement STL Deque

---

- Capacity:
  - (**size**) Return size (public member function)
  - (**max\_size**) Return maximum size (public member function)
  - (**resize**) Change size (public member function)
  - (**empty**) Test whether vector is empty (public member function)
  - (**shrink\_to\_fit**) Shrink to fit (public member function)
- Element access:
  - (**operator[]**) Access element (public member function)
  - (**at**) Access element (public member function)
  - (**front**) Access first element (public member function)
  - (**back**) Access last element (public member function)

# Implement STL Deque

- **Modifiers:**
  - (**assign**) Assign vector content (public member function)
  - (**push\_back**) Add element at the end (public member function)
  - (**push\_front**) Insert element at beginning (public member function)
  - (**pop\_back**) Delete last element (public member function)
  - (**pop\_front**) Delete first element (public member function)
  - (**insert**) Insert elements (public member function)
  - (**erase**) Erase elements (public member function)
  - (**swap**) Swap content (public member function)
  - (**clear**) Clear content (public member function)
