Lecture 6 Deque Linked List Based

Course Roadmap

Part 1: Linear Data Structures

Lecture 1: Complexity Analysis & Recursion

Lecture 2: Arrays

Lecture 3: Linked List

Lecture 4: Stack

Lecture 5: Queue

Lecture 6: Deque

Lecture 7: STL in C++ (Linear Data Structures)

Lecture Agenda

We will discuss in this lecture the following topics

- 1- Introduction to Deque
- 2- Insertion Operation
- 3- Deletion Operation
- 4- Front & Back Operations
- 5- Traverse Operation
- 6- Time Complexity & Space Complexity

4

Lecture Agenda

Section 1: Introduction to Deque

Section 2: Insertion Operation

Section 3: Deletion Operation

Section 4: Front & Back Operations

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

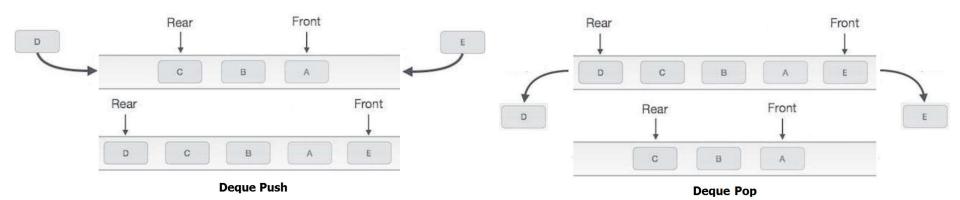

Introduction to Deque

- A double-ended queue (abbreviated to deque) is an abstract data type that generalizes a queue, for which elements can be added to or removed from either the front (head) or back (tail). It is also often called a head-tail linked list.
- A deque, also known as a double-ended queue, is an ordered collection of items similar to the queue. It has two ends, a front and a rear, and the items remain positioned in the collection. What makes a deque different is the unrestrictive nature of adding and removing items. New items can be added at either the front or the rear. Likewise, existing items can be removed from either end. In a sense, this hybrid linear structure provides all the capabilities of stacks and queues in a single data structure.
- A deque, also known as a double-ended queue where by it has two ends, a front and a rear, and the items remain positioned in the collection. New items can be added or removed at either the front or the rear. It does not require the LIFO and FIFO orderings that are enforced by those data structures. It is up to you to make consistent use of the addition and removal operations.

Introduction to Deque

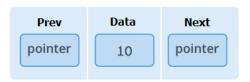

- CODEFORCES AtCoder
- Deque operations may involve initializing or defining the deque, utilizing it, and then completely erasing it from the memory. Here we shall try to understand the basic operations associated with deques
- insert begin() adds a new item to the front of the deque.
- insert end() adds a new item to the rear of the deque.
- delete begin() removes the front item from the deque.
- delete end() removes the rear item from the deque.

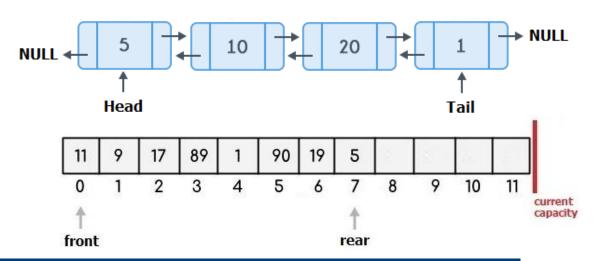

Introduction to Deque

CODEFORCES AtCoder

- Following are the basic operations supported by a deque.
- Insert (begin & end) adds a new item to the front & rear of the deque.
- Delete (begin & end) removes the front & rear item from the deque.
- Front & Back: which gets the first element and the last element in the queue.
- Deque Types
- 1. Deque (Linked List Based)

2. Deque (Array Based)

Deque (Linked List Based) Node

Initialize a global struct

```
#include <bits/stdc++.h>
using namespace std;
// A deque node
struct node {
    int data;
    node* prev;
    node* next;
};
  Initialize a global pointers for head and tail
node* head;
node* tail;
```

Lecture Agenda

✓ Section 1: Introduction to Deque

Section 2: Insertion Operation

Section 3: Deletion Operation

Section 4: Front & Back Operations

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

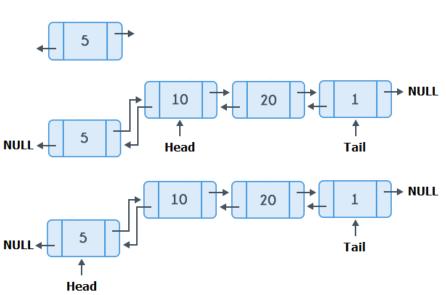

CODEFORCES AtCoder

 Insert Operation is to add (store) an item to the deque.

Insert at begin 5

NULL 4 10 20 1 NULL Head Tail

- Insertion Algorithm:
- 1. create a new node
- 2. new node data = data
- 3. if head == NULL then head = new node
- 4. tail = new node
- 5. otherwise new node next = head
- 6. head prev = new node
- 7. head = new node

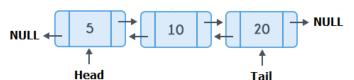

```
CODEFORCES AtCoder
```

```
This function inserts a node at the begin of the deque
void insert begin(int new data) {
    // allocate new node and put it's data
    node* new node = new node();
    new node->data = new data;
    // check if the deque is empty
    if (head == NULL) {
       head = new node;
        tail = new node;
      otherwise insert the new node in the begin of the deque
    else {
        // set next of the new node to be the head and vice versa
        new node->next = head;
        head->prev = new node;
        // set the new node as a head
        head = new node;
```

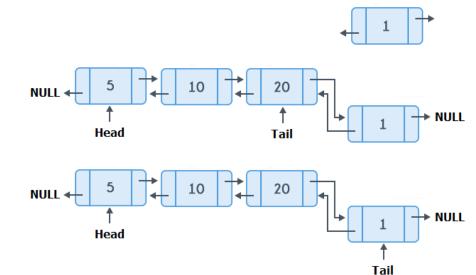

CODEFORCES

 Insert Operation is to add (store) an item to the deque. Insert at end 1

- Insertion Algorithm:
- 1. create a new node
- 2. new node data = data
- 3. if head == NULL then head = new node
- 4. tail = new node
- 5. otherwise new node prev = tail
- 6. tail next = new node
- 7. tail = new node

```
CODEFORCES AtCoder
```

```
This function inserts a node at the end of the deque
void insert end(int new data) {
    // allocate new node and put it's data
    node* new node = new node();
    new node->data = new data;
    // check if the deque is empty
    if (head == NULL) {
       head = new node;
        tail = new node;
      otherwise reach the end of the deque
    else {
        // set the next of the last node to be the new node and vice versa
        tail->next = new node;
        new node->prev = tail;
        // set the new node as a tail
        tail = new node;
```

Lecture Agenda

- ✓ Section 1: Introduction to Deque
- ✓ Section 2: Insertion Operation

Section 3: Deletion Operation

Section 4: Front & Back Operations

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

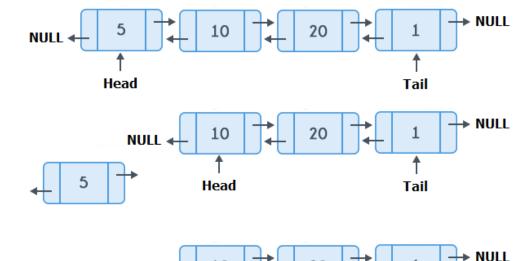

Delete at begin 5

- **Deletion Algorithm:**
- 1. temp node = head
- 2. if head equal tail then
- 3. delete temp node
- head = tail = NULL
- $otherwise\ head = head\ next$
- 6. head prev = NULL
- delete temp node

10

Head

NULL **←**

20

Tail

```
CODEFORCES At Coder
```

```
This function deletes the first node in the deque
void delete begin() {
   // check if the deque is empty
    if (head == NULL)
        return:
   // get the node which it will be deleted
   node* temp node = head;
   // check if the degue contain only one node
    if (head == tail) {
        delete(temp node); // delete the temp node
        head = tail = NULL;
      otherwise the deque contain nodes more than one
   else {
        // shift the head to be the next node
        head = head->next;
        head->prev = NULL;
        delete(temp node); // delete the temp node
```

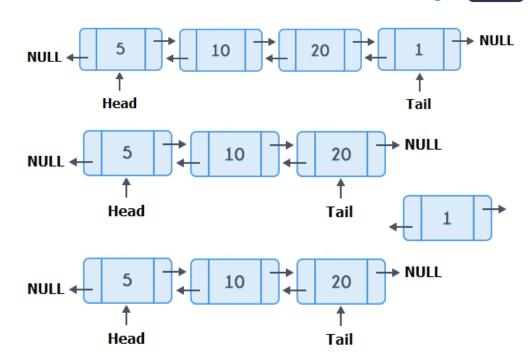

18

CODEFORCES AtCoder

• Delete Operation remove (access) an item from the queue.

- Deletion Algorithm:
- 1. temp node = tail
- 2. if head equal tail then
- 3. delete temp node
- 4. head = tail = NULL
- 5. $otherwise\ tail = tail\ prev$
- 6. $tail\ next = NULL$
- 7. delete temp node

• Delete at end 1

```
CODEFORCES At Coder
```

```
This function deletes the last node in the deque
void delete end() {
   // check if the deque is empty
    if (head == NULL)
        return;
   // get the node which it will be deleted
   node* temp node = tail;
   // check if the deque contain only one node
    if (head == tail) {
       delete(temp_node); // delete the temp node
       head = tail = NULL:
   // otherwise the deque contain nodes more than one
    else {
       // jump the deleted node
        tail = tail->prev;
       tail->next = NULL;
        delete(temp_node); // delete the node which selected
```

Lecture Agenda

- ✓ Section 2: Insertion Operation
- ✓ Section 3: Deletion Operation

Section 4: Front & Back Operations

Section 5: Traverse Operation

Section 6: Time Complexity & Space Complexity

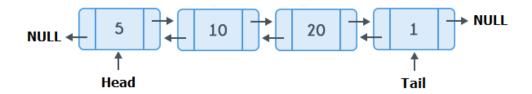

Front & Back Operations - Deque (Linked List Based)

CODEFORCES AtCoder

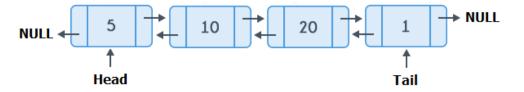

- Front Operation gets the first item in the deque.
- Front 5

- Front Algorithm:
- 1. return head

- Back Operation gets the last item in the deque.
- Back 1

- Back Algorithm:
- 1. return tail

Front & Back Operations - Deque (Linked List Based)

```
CODEFORCES AtCoder
```

```
This function returns the value of the first element in the deque
int front() {
    // check if the deque is empty
    // to return the biggest integer value as an invalid value
    if (head == NULL)
        return INT MAX;
    // otherwise return the real value
    else
        return head->data;
   This function returns the value of the last element in the deque
int back() {
    // check if the deque is empty
    // to return the biggest integer value as an invalid value
    if (tail == NULL)
        return INT MAX;
    // otherwise return the real value
    else
        return tail->data:
```

Lecture Agenda

- ✓ Section 2: Insertion Operation
- ✓ Section 3: Deletion Operation
- ✓ Section 4: Front & Back Operations

Section 5: Traverse Operation

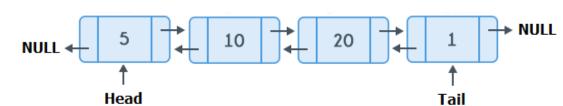

Section 6: Time Complexity & Space Complexity

Traverse Operation - Deque (Linked List Based)

 Traverse Operation You start at the head of the list and continue until you come across a node that is. • Traverse this deque

- Traverse Algorithm:
- 1. curr = head
- 2. print curr data
- 3. curr = curr next
- 4. Repeat Step 2 if curr not equal NULL

Traverse Operation - Deque (Linked List Based)

```
CODEFORCES At Coder
```

```
// This function prints the contents of the deque
void print deque() {
    // print the data nodes starting from head till reach the last node
   node* curr = head:
    while (curr != NULL) {
        cout << curr->data << ' ':
        curr = curr->next;
  This function prints the contents of the deque
void print deque reverse() {
    // print the data nodes starting from tail till reach the first node
    node* curr = tail;
    while (curr != NULL) {
        cout << curr->data << ' ':
        curr = curr->prev;
```

Initialize a global struct

```
#include <bits/stdc++.h>
using namespace std;
// A deque node
struct node {
    int data;
    node* prev;
    node* next;
};
   Initialize a global pointers for head and tail
node* head;
node* tail;
```

cout << "the above elements have been added to the deque\n";</pre>

➤ In the Main function:

```
cout << "Deque front: " << front() << " and Deque back: " << back() << '\n';</pre>
cout << "Deque items forward: ";</pre>
print deque();
                                           Deque front: 2147483647 and Deque back: 2147483647
cout << '\n';
                                           Deque items forward:
cout << "Deque items backward: ";</pre>
                                           Deque items backward:
print deque reverse();
cout << '\n';
cout << "adding the following elements 10 20 30 40 50\n";
insert end(10);
                                           adding the following elements 10 20 30 40 50
insert end(20);
                                           the above elements have been added to the deque
insert end(30);
insert end(40);
insert end(50);
```

➤ In the Main function:

cout << '\n';

```
cout << "Deque front: " << front() << " and Deque back: " << back() << '\n';</pre>
cout << "Deque items forward: ";</pre>
print deque();
                                           Degue front: 10 and Degue back: 50
cout << '\n';
                                           Degue items forward: 10 20 30 40 50
cout << "Deque items backward: ";
                                           Degue items backward: 50 40 30 20 10
print deque reverse();
cout << '\n';
cout << "add element 60 at the end of the deque\n";</pre>
insert end(60);
                                           add element 60 at the end of the deque
cout << "Deque front: " << front() << " and Deque back: " << back() << '\n';</pre>
cout << "Deque items forward: ";</pre>
                                           Deque front: 10 and Deque back: 60
print deque();
                                           Deque items forward: 10 20 30 40 50 60
cout << '\n';
                                           Deque items backward: 60 50 40 30 20 10
cout << "Deque items backward: ";</pre>
print deque reverse();
```

```
cout << "adding the following elements 40 30 20 10\n";
insert begin (10);
                                               adding the following elements 40 30 20 10
insert begin (20);
                                               the above elements have been added to the deque
insert begin (30);
insert begin (40);
cout << "the above elements have been added to the deque\n";
cout << "Deque front: " << front() << " and Deque back: " << back() << '\n';</pre>
cout << "Deque items forward: ";</pre>
                                           Degue front: 40 and Degue back: 10
print deque();
                                           Deque items forward: 40 30 20 10
cout << '\n';
                                           Deque items backward: 10 20 30 40
cout << "Deque items backward: ";</pre>
print deque reverse();
cout << '\n';
```

Functionality Testing - Deque (Linked List Based)

➤ In the Main function:

cout << '\n';

Expected Output:

```
cout << "deleting the following elements 40 30 20 10\n";</pre>
delete begin();
                                           deleting the following elements 40 30 20 10
delete begin();
                                           the above elements have been deleted from the deque
delete begin();
delete begin();
cout << "the above elements have been deleted from the deque\n";</pre>
cout << "Deque front: " << front() << " and Deque back: " << back() << '\n';</pre>
cout << "Deque items forward: ";</pre>
                                            Deque front: 2147483647 and Deque back: 2147483647
print deque();
                                            Deque items forward:
cout << '\n';
                                            Deque items backward:
cout << "Deque items backward: ";</pre>
print deque reverse();
```

CODEFORCES At Coder

- 1- Reverse string using stack
- 2- Check string is palindrome or not
- 3- Convert Infix Expression to Postfix Expression
- 4- Convert Infix Expression to Prefix Expression
- 5- Convert Postfix Expression to Infix Expression
- 6- Convert Prefix Expression to Infix Expression
- 7- Convert Postfix Expression to Prefix Expression
- 8- Convert Prefix Expression to Postfix Expression
- 9- Evaluation of Postfix Expression
- 10- Reverse a stack using recursion
- 11- Check for balanced parentheses in an expression
- 12- Length of the longest valid substring
- 13- Minimum number of bracket reversals needed to make an expression balanced
- 14- Next Greater Element
- 15- Delete middle element of a stack

CODEFORCES At Coder

- 16- Reverse individual words
- 17- Largest Rectangular Area in a Histogram
- 18- Find maximum depth of nested parenthesis in a string
- 19- Expression contains redundant bracket or not
- 20- Check if two expressions with brackets are same
- 21- Delete consecutive same words in a sequence
- 22- Remove brackets from an algebraic string
- 23- Range Queries for Longest Correct Bracket Subsequence
- 24- Check if stack elements are pairwise consecutive
- 25- Reverse a number using stack
- 26- Tracking current Maximum Element in a Stack
- 27- Decode a string recursively encoded as count followed by substring
- 28- Find maximum difference between nearest left and right smaller elements
- 29- Find if an expression has duplicate parenthesis or not
- 30- Find index of closing bracket for a given opening bracket in an expression

CODEFORCES AtCoder

- 31- Sliding Window Maximum summation of all sub-arrays of size k
- 32- Check string is palindrome or not
- 33- Generate Binary Numbers from 1 to n
- 34- Reversing a queue using recursion
- 35- Reversing the first K elements of a Queue
- 36- Find the largest multiple of 3
- 37- Smallest multiple of a given number made of digits 0 and 9 only
- 38- Delete all elements in the deque
- 39- Sum of minimum and maximum elements of all subarrays of size k
- 40- First negative integer in every window of size k

Assignment

- Deque (usually pronounced like "deck") is an irregular acronym of double-ended queue. Double-ended queues are sequence containers with dynamic sizes that can be expanded or contracted on both ends (either its front or its back).
- Specific libraries may implement deques in different ways, generally as some form of dynamic array. But in any case, they allow for the individual elements to be accessed directly through random access iterators, with storage handled automatically by expanding and contracting the container as needed.
- Therefore, they provide a functionality similar to vectors, but with efficient insertion and deletion of elements also at the beginning of the sequence, and not only at its end. But, unlike vectors, deques are not guaranteed to store all its elements in contiguous storage locations: accessing elements in a deque by offsetting a pointer to another element causes undefined behavior.
- Double ended queues are sequence containers with the feature of expansion and contraction on both the ends. They are similar to vectors, but are more efficient in case of insertion and deletion of elements. Unlike vectors, contiguous storage allocation may not be guaranteed.

- Both vectors and deques provide a very similar interface and can be used for similar purposes, but internally both work in quite different ways: While vectors use a single array that needs to be occasionally reallocated for growth, the elements of a deque can be scattered in different chunks of storage, with the container keeping the necessary information internally to provide direct access to any of its elements in constant time and with a uniform sequential interface (through iterators). Therefore, deques are a little more complex internally than vectors, but this allows them to grow more efficiently under certain circumstances, especially with very long sequences, where reallocations become more expensive.
- Double Ended Queues are basically an implementation of the data structure double ended queue. A queue data structure allows insertion only at the end and deletion from the front. This is like a queue in real life, wherein people are removed from the front and added at the back. Double ended queues are a special case of queues where insertion and deletion operations are possible at both the ends. The functions for deque are same as vector, with an addition of push and pop operations for both front and back.

CODEFORCES AtCoder

Member functions: (constructor) Construct vector (public member function)

(destructor) Vector destructor (public member function)

(operator=) Assign content (public member function)

Iterators: (begin) Return iterator to beginning (public member function)

(end) Return iterator to end (public member function)

(rbegin) Return reverse iterator to reverse beginning (public member function)

(rend) Return reverse iterator to reverse end (public member function)

(cbegin) Return const<u>i</u>terator to beginning (public member function)

(cend) Return const_iterator to end (public member function)

(crbegin) Return const_reverse_iterator to reverse beginning (public member function)

(crend) Return const_reverse_iterator to reverse end (public member function)

CODEFORCES At Coder

Capacity: (size) Return size (public member function)

(max_size) Return maximum size (public member function)

(resize) Change size (public member function)

(empty) Test whether vector is empty (public member function)

(shrink to fit (public member function)

• Element access: (operator[]) Access element (public member function)

(at) Access element (public member function)

(front) Access first element (public member function)

(back) Access last element (public member function)

CODEFORCES

Modifiers:

(assign) Assign vector content (public member function)
(push_back) Add element at the end (public member function)
(push_front) Insert element at beginning (public member function)
(pop_back) Delete last element (public member function)
(pop_front) Delete first element (public member function)
(insert) Insert elements (public member function)
(erase) Erase elements (public member function)
(swap) Swap content (public member function)
(clear) Clear content (public member function)
